#### Ultra-High Energy Cosmic Rays : a Window to Post-Inflationary Reheating Epoch of the Universe ?

#### V.A. Kuzmin and V.A. Rubakov

Institute for Nuclear Research of Russian Academy of Sciences, 60th October Anniversary Prosp. 7a, Moscow 117312, Russia E-mails : kuzmin@ms2.inr.ac.ru, rubakov@ms2.inr.ac.ru

#### Abstract

We conjecture that the highest energy cosmic rays,  $E > E_{GZK}$ , where  $E_{GZK} \sim 5 \cdot 10^{19}$ eV is the Greisen–Zatsepin–Kuzmin cut-off energy of cosmic ray spectrum, may provide a unique window into the very early epoch of the Universe, namely, that of reheating after inflation, provided these cosmic rays are due to decays of parent superheavy long-living X-particles.

These particles may constitute a considerable fraction of cold dark matter in the Universe. We argue that the unconventionally long lifetime of the superheavy particles, which should be in the range of  $10^{10} - 10^{22}$  years, might require novel particle physics mechanisms of their decays, such as instantons. We propose a toy model illustrating the instanton scenario.

Generic expected features of ultra-high energy extensive air showers in our scenario are similar to those of other top-down scenarios. However, some properties of the upper part of the cosmic ray spectrum make the instanton scenario distinguishable, at least in principle, from other ones.

#### Ultra-high energy cosmic rays without GZK cutoff

V. Berezinsky<sup>1</sup>, M. Kachelrieß<sup>1</sup>, and A.Vilenkin<sup>2</sup>

<sup>1</sup>INFN, Laboratori Nazionali del Gran Sasso, I-67010 Assergi (AQ), Italy
<sup>2</sup>Institute of Cosmology, Department of Physics and Astronomy, Tufts University, Medford, MA 02155, USA

We study the decays of ultraheavy  $(m_X \ge 10^{13} \text{ GeV})$  and quasistable (lifetime  $\tau_X$  much larger than the age of the Universe  $t_0$ ) particles as the source of Ultra High Energy Cosmic Rays (UHE CR). These particles are assumed to constitute a tiny fraction  $\xi_X$  of CDM in the Universe, with  $\xi_X$ being the same in the halo of our Galaxy and in the intergalactic space. The elementary-particle and cosmological scenarios for these particles are briefly outlined. The UHE CR fluxes produced at the decays of X- particles are calculated. The dominant contribution is given by fluxes of photons and nucleons from the halo of our Galaxy and thus they do not exibit the GZK cutoff. The extragalactic components of UHE CR are suppressed by the smaller extragalactic density of X-particles and hence the cascade limit is relaxed. We discuss the spectrum of produced Extensive Air Showers (EAS) and a signal from Virgo cluster as signatures of this model.

PACS numbers: 98.70.Sa, 14.80.-j

The observations of Ultra-High Energy Cosmic Rays (UHE CR) reveal the presence of a new, isotropic component at energies  $E \ge 1 \cdot 10^{10}$  GeV (for a review see Ref. []). This component is thought to have an extragalactic phenomenological approach and treat the density  $n_X$  of X-particles and their lifetime  $\tau_X$  as free parameters fixed only by the requirement that the observed UHE CR flux is reproduced. We calculate the fluxes of nucleons, pho-

#### Status of fragmentation functions

We may further estimate the spectrum of hadrons and secondary photons, though here we are on somewhat thinner ice. The exact x-distribution for fragmentation of a gluon jet is not known, and only a few properties, such as the total multiplicity and more recent observations of a peak at very low x have been determined [7]. Indeed, it is not clear how much can be determined theoretically. For our purposes the important features are to realize the correct multiplicity, assure that the first moment of the distribution be normalized properly to unity, and try to guess the correct large-x behavior, which we take to be  $(1 - x)^2$ . We will build the multiplicity into the low-x behavior of the distribution. For the leading log QCD multiplicity formula

### Fragmentation function in Gaussian approx. and SUSY

VOLUME 79, NUMBER 26

PHYSICAL REVIEW LETTERS

29 DECEMBER 1997

#### Cosmic Necklaces and Ultrahigh Energy Cosmic Rays

Veniamin Berezinsky<sup>1</sup> and Alexander Vilenkin<sup>2</sup> <sup>1</sup>INFN, Laboratori Nacionali del Gran Sasso, 67010 Assergi (AQ), Italy <sup>2</sup>Institute of Cosmology, Departmento of Physics and Astronomy, Tulky University, Medford, Massachusetts 02155 (Received 28 April 1997; revised manuscript received 15 October 1997)

The fragmentation function is calculated using the decay of X particle into QCD partons (quark, gluons, and their supersymmetric partners) with the consequent development of the parton cascade. We have used the fragmentation function in the Gaussian form as obtained in the modified leading logarithm approximation in [19,20]. Additionally, we took into account the supersymmetric corrections to the coupling constant  $\alpha_s$  at large  $Q^2$ . The explicit form of the fragmentation function at small x is found as

$$W_N(m_X, x) = \frac{K_N}{x} \exp\left(-\frac{\ln^2 x/x_m}{2\sigma^2}\right),$$
 (5)

where  $2\sigma^2 = (1/6) [\ln(m_X/\Lambda)]^{3/2}$ ,  $x = E/m_X$ ,  $x_m = (\Lambda/m_X)^{1/2}$ ,  $\Lambda = 0.234$  GeV with the normalization constant  $K_N$  to be found from energy conservation assuming that about 10% of initial energy  $(m_X)$  is transferred to nucleons.

## Conclusions

- WIMP paradigm in crisis ⇒ mass range of DM is wide open
- SHDM is an interesting DM candidate
  - Gravitational creation of DM with  $m_X \sim 10^{11}$
  - probes inflation & GUT physics
  - photon & neutrino searches most promising
- SUSY-QCD & electroweak bremsstrahlung: now included in "standard" MC simulations
- illustrates nicely Venya's way to do physics
